# ECE 133A HW 4

#### Lawrence Liu

November 10, 2022

## Exercise T13.3

(a)

#### With the following julia code we get:

```
using MAT
using LinearAlgebra
using PyPlot
# using Statistics

include("mooreslaw.m")
# println(T)
Years, Transistors=T[:,1],T[:,2]
# println(Years)
# println(Transistors)
A=transpose([reshape(ones(size(Years)),1,:);reshape(Years.-1970,1,:)])
# println(A)
log_Transistors=log10.(Transistors)
theta=A\log_Transistors
println("theta_1=",theta[1])
println("theta_2=",theta[2])
#plot out
plot(Years,log_Transistors,"o")
plot(Years,A*theta)
xlabel("Years")
ylabel("Transistors (log10)")
title("Moore's Law")
legend(["Data","Fit"])
savefig("Moore's Law.png")
close()
```

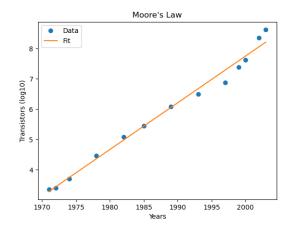

that

 $\theta_1 = 3.125592633829346$ 

and

$$\theta_2 = 0.1540181798438225$$

which results in the following fit:

(b)

From our fit we expect the number of transistors to be:

$$10^{\theta_1 + \theta_2(2015 - 1970)} \approx 10^{10}$$

Which is more than the acutally number of  $4\cdot 10^9$  transistors:

(c)

This is in line with Moore's law since  $2\theta_2=0.30803635968$  which is close to  $\log_{10}(2)=0.30102999566$ 

### Exercise T12.12

(a)

Let  $p_{ik} = [u_{ik}, v_{ik}]$  then we have that

$$||p_{i_1} - pj_1||^2 + \dots + ||p_{i_L} - p_{j_L}||^2 = (u_{i_1} - u_{j_1})^2 + \dots + (u_{i_L} - u_{j_L})^2 + (v_{i_1} - v_{j_1})^2 + \dots + (v_{i_L} - v_{j_L})^2$$

$$||p_{i_1} - pj_1||^2 + \dots + ||p_{i_L} - p_{j_L}||^2 = D(u) + D(v)$$

(b)

we have that we want to minimize

$$||B^T u||^2 + ||B^T v||^2$$

Letting the matrix made up of the of the first N-K rows of B be the matrix A and the last K rows of B, likewise let  $u_1$  and  $v_1$  be the first N-K rows of u and v and v

$$||B^{T}u||^{2} + ||B^{T}v||^{2} = ||A^{T}u_{1} + B^{T}u_{2}||^{2} + ||A^{T}v_{1} + B^{T}v_{2}||^{2}$$

$$= \left| \left| \begin{bmatrix} A^{T} & 0 \\ 0 & A^{T} \end{bmatrix} \begin{bmatrix} u_{1} \\ v_{1} \end{bmatrix} + \begin{bmatrix} B^{T}u_{2} \\ B^{T}v_{2} \end{bmatrix} \right| \right|^{2}$$

So then we have that in term of a least square problem we have  $||Ax - b||^2$ 

$$A = \begin{bmatrix} A^T & 0 \\ 0 & A^T \end{bmatrix}$$

And

$$b = \begin{bmatrix} B^T u_2 \\ B^T v_2 \end{bmatrix}$$

And

$$x = \begin{bmatrix} u_1 \\ v_1 \end{bmatrix}$$

(c)

#### Exercise A8.3

We can get that

$$\alpha t_i + \beta = \ln(\frac{y_i}{1 - y_i})$$

So therefore we can have a least squares problem, with

$$A = \begin{bmatrix} t_1 & 1 \\ t_2 & 1 \\ \vdots & \vdots \\ t_n & 1 \end{bmatrix}$$

and

$$b = [\ln(\frac{y_1}{1 - y_1}), \ln(\frac{y_2}{1 - y_2}), \dots, \ln(\frac{y_n}{1 - y_n})]^T$$

and

$$x = [\alpha, \beta]^T$$

Then we have a least squares problem of

$$||Ax - b||^2$$

To find  $\alpha$  and  $\beta$  I used the following code:

```
using PyPlot
include("logistic_fit.jl")

t ,y=logistic_fit()

A=ones(length(t),2)
A[:,1]= t
b=log.(y./(ones(length(t)).-y))

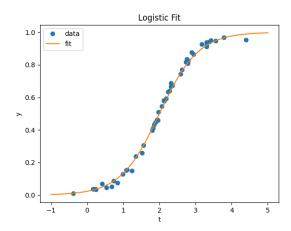

x=A\b
# println(x)
# println(x[1].*t)
# println(x[2])
t1=LinRange(-1,5,50)
y1=exp.(x[2].+(x[1].*t1))./(ones(length(t1)).+exp.(x[2].+(x[1]*t1)))
println("alpha=",x[1])
println("beta=",x[2])
plot(t,y,"o",label="data")
plot(t1,y1,label="fit")
xlabel("t")
ylabel("y")
title("Logistic Fit")
legend()
savefig("fig2.png")
close()
```

### which results in

 $\alpha = 1.8676293241597044$ 

 $\beta = -3.739673238861126$ 

## and the following fit:

#### Exercise A5.11

(a)

we have that

$$x = A^{\dagger}b$$

$$x = (A^{T}A)^{-1}A^{T}b$$

$$x = \left(\begin{bmatrix} 1 & 10^{-k} & 0 \\ 1 & 0 & 10^{-k} \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 10^{-k} & 0 \\ 0 & 10^{-k} \end{bmatrix} \right)^{-1} \begin{bmatrix} 1 & 10^{-k} & 0 \\ 1 & 0 & 10^{-k} \end{bmatrix} \begin{bmatrix} -10^{-k} \\ 1+10^{-k} \\ 1-10^{-k} \end{bmatrix}$$

$$x = \left(\begin{bmatrix} 1+10^{-2k} & 1 \\ 1 & 1+10^{-2k} \end{bmatrix} \right)^{-1} \begin{bmatrix} 10^{-2k} \\ -10^{-2k} \end{bmatrix}$$

$$x = \begin{bmatrix} \frac{1+10^{-2k}}{10^{-4k}+2\cdot10^{-2k}} & -\frac{1}{10^{-4k}+2\cdot10^{-2k}} \\ -\frac{1}{10^{-4k}+2\cdot10^{-2k}} & \frac{1+10^{-2k}}{10^{-4k}+2\cdot10^{-2k}} \end{bmatrix} \begin{bmatrix} 10^{-2k} \\ -10^{-2k} \end{bmatrix}$$

$$x = \frac{10^{-2k}}{10^{-4k}+2\cdot10^{-2k}} \begin{bmatrix} 2+10^{-2k} \\ -2-10^{-2k} \end{bmatrix}$$

thus we have for k = 6:

$$x = \frac{10^{-12}}{10^{-24} + 2 \cdot 10^{-12}} \begin{bmatrix} 2 + 10^{-12} \\ -2 - 10^{-12} \end{bmatrix}$$

And for k = 7 we have

$$x = \frac{10^{-14}}{10^{-28} + 2 \cdot 10^{-14}} \begin{bmatrix} 2 + 10^{-14} \\ -2 - 10^{-14} \end{bmatrix}$$

And for k = 8 we have

$$x = \frac{10^{-16}}{10^{-32} + 2 \cdot 10^{-16}} \begin{bmatrix} 2 + 10^{-16} \\ -2 - 10^{-16} \end{bmatrix}$$

(b)

We have that with the following code:

```
for k = [6,7,8]
    A=transpose([[1,1] [10.0^-k,0] [0,10.0^-k]])
    b = [-(10.0^{\circ} - k), 1 + 10.0^{\circ} - k, 1 - 10.0^{\circ} - k]
    println("k=",k)
    println("x=",A\b)
    println("----
end
we get that
k=6
x = [0.999999999176988, -0.99999999917699]
x=[1.0000000027436178, -1.0000000027436176]
x=[1.0000000043137076, -1.0000000043137076]
(c)
We have that with the following code:
for k = [6,7,8]
    A=transpose([[1,1] [10.0^-k,0] [0,10.0^-k]])
    b = [-(10.0^{\circ} - k), 1 + 10.0^{\circ} - k, 1 - 10.0^{\circ} - k]
    println("k=",k)
    println("x=",(A'*A) \setminus (A'*b))
    println("_____")
end
```

we get that

And for k=8 we get a singular exception error since  $\mathbf{A'*A}$  gets rounded to a matrix  $\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$  that is singular

(a)

$$f(y) = ||Ay - b||^2 + (c^T y - d)^2$$

To minimize we take the derivative of it with respect to  $y_i$  for all  $1 \le n \le N$  and set it to zero have

$$\frac{\partial}{\partial y_i} f(y) = 2(A^T (Ay - b))_i + 2(c^T y - d)c_i = 0$$

Thus we have

$$\nabla f(y) = 2(A^{T}(Ay - b) + c(c^{T}y - d)) = 0$$

which gives us

$$\nabla f(y) = 0$$
$$2(A^{T}(Ay - b) + c(c^{T}y - d)) = 0$$
$$A^{T}(Ay - b) + c(c^{T}y - d) = 0$$

if  $\hat{y}$  is a solution then we must have that

$$A^{T}(A\hat{y} - b) + c(c^{T}\hat{y} - d) = 0$$

we can confirm this, since

$$\hat{y} = \hat{x} + \frac{d - c^T \hat{x}}{1 + c^T (A^T A)^{-1} c} (A^T A)^{-1} c$$

we have:

$$A^{T}(A\hat{y}-b) + c(c^{T}\hat{y}-d) = 0$$

$$A^{T}A\frac{d-c^{T}\hat{x}}{1+c^{T}(A^{T}A)^{-1}c}(A^{T}A)^{-1}c + cc^{T}\hat{x} + c(c^{T}\frac{d-c^{T}\hat{x}}{1+c^{T}(A^{T}A)^{-1}c}(A^{T}A)^{-1}c - d) = 0$$

$$dc - c^{T}\hat{x}c + cc^{T}(d-c^{T}\hat{x})(A^{T}A)^{-1}c - c(d-c^{T}\hat{x})(1+c^{T}(A^{T}A)^{-1}c) = 0$$

$$cc^{T}(d-c^{T}\hat{x})(A^{T}A)^{-1}c - c(d-c^{T}\hat{x})(c^{T}(A^{T}A)^{-1}c) = 0$$

$$cc^{T}(d-c^{T}\hat{x})(A^{T}A)^{-1}c - cc^{T}(d-c^{T}\hat{x})(A^{T}A)^{-1}c = 0$$

(b)

We first compute the QR factorization fo A, which will cost us  $2mn^2$  flops, then we can compute  $\hat{x}$  with an additional  $2mn+n^2$  flops. Likewise, since we can rewrite  $(A^TA)^{-1}c$  as  $(R^TQ^TQR)^{-1}c=(R^TR)^{-1}c$ , which we can solve in  $2n^2$  flops. then computing  $c^T\hat{x}$  and  $c^T(A^TA)^{-1}c$  will each cost us an additional 2n-1 flops, then computing  $\frac{d-c^T\hat{x}}{1+c^T(A^TA)^{-1}c}$  will cost us 3 flops. Then computing  $\hat{x}+\frac{d-c^T\hat{x}}{1+c^T(A^TA)^{-1}c}(A^TA)^{-1}c$  will cost us 2n flops, so in total this algorithm will cost us  $2mn^2+2mn+3n^2+6n-1$  flops.
